

Case Study

A contribution to flora, life forms and chorology of plants (Case study: South West Ardabil province, Iran)

ABSTRACT

Floristic studies are fundamental for the applied sciences such as rangeland management and conservation. Unique ecological and climatic conditions in the South West Ardabil Province (SWA) make it a remarkable habitat for the floristic studies. Plant species were collected from 50 field sites, representing major habitats of winter and rural rangelands. Surveys were conducted during active growth periods in 2012 and 2013. Plant species were identified and their chorology and life form determined through laboratory examinations and by using reference books. Floristic surveys resulted in identification of 534 plant species, belonged to 315 genus and 68 families. Asteraceae, Poaceae and Fabaceae were respectively the most abundant plant families. Among the life forms, Hemicryptophytes, Therophytes, Chamaephytes, Phanerophytes and Geophytes included 45, 32, 9, 7 and 7% of the total species, respectively. Irano-Turanian was the most dominant (65%) Chorotypes. The dominance of Hemicryptophytes and Therophytes, as well as vast distribution of Chamaephytes, can be referred to the simultaneous effects of climate fluctuations and livestock grazing on the flora of winter and rural rangelands in SWA.

Keywords: Rangeland, Floristic composition, South West Ardabil, Iran.

INTRODUCTION

Iran is known as one of the most appealing places for studying plant diversity, as 22% of its 8000 plant species are endemic (Asri 2000). Identifying flora of each region is fundamental for accomplishing other pure and applied researches in biology. Especially in the South West Ardabil (SWA), unique ecological and climatic conditions make it a remarkable habitat for the floristic studies. Winter and rural rangelands comprise a large fraction of SWA area. People in this region are highly dependent on rangelands; they use range plants as sources for food, medicine, livestock production etc. Therefore, identifying floristic list of rural and winter rangelands of SWA is beneficial for protecting the endangered plants, and for planning a sustainable use of forage, ornamental and medicinal plants. Several reference books (e.g. Rechinger 1967-2010; Boissier 1867-

1888; Assadi et al., 2001-2010) provide valuable information on the native and exotic plants of SWA. However, they are mainly adopted from the large-scale studies and do not provide detailed information on the flora of this region. On the other hand several studies have been conducted on the flora of SWA (e.g. Shaad and Sanjari 2011; Aydani 2004; Sobhani et al., 2007) but they only represent information on the flora small areas (usually less than 10000 hectares). Akhavi (2009) have studied flora of Golestan National Park, in which small parts of Germeh and Maneh-o-Samalghan counties were also included. Other researchers have studied geographic distribution of plant species for only one family or one genus in Ardabil Provinces, e.g. Compositae (Sobhani and Rajamand, 2007), (Cupressaceae Sadeghalnejat 2007), and genus of Bromus L. (Memariani and

Joharchi, 2007). Accordingly, a lack of comprehensive information on the flora rural and winter rangelands of SWA was the most important reason behind this research. The main aim was to do a survey the flora and to identify the major plant phenotype and chorotypes of the winter and rural rangelands in SWA. Result of this study can also be used for the applied researches such as rangeland management and conservation.

MATERIALS AND METHODS

South West Ardabil Province is located between $45^{\circ} 36'$ to $26^{\circ} 39'$ northern latitude and $5^{\circ} 45'$ to $22^{\circ} 48'$ eastern longitude. It is located in the northwest of Iran, and comprised of six counties i.e. Kaleybar, Khoda afarin, Ahar, Varzaqan, Jolfa and Marand. Rangelands contain 55.82% of SWA area, which is about 1.72 million hectares, from which 1.31 million hectares are used as winter and rural rangelands (Jankju et al., 2009).

Main bioclimatic region in SWA is Irano-Turanian that is distinguished by hot and dry summers, wet and cold winters. The region is also influenced by cold and dry winds from Siberia (north) and wet and mild climate from the Caspian Sea (west). Therefore the flora of SWA are affected by sever climate fluctuations, because of interaction between the three major climatic regimes. Average yearly rainfall varies from the lowest (<300 mm) in Marand to the highest (650 mm) in the northwest of Kaleybar. Average annual temperature also varies from a maximum (17-18 °C) in Varzaqan to the minimum (8-10 °C) values in Khoda afarin. Many places of SWA winter and rural rangelands confer similar climate, geology and topography conditions. Therefore, site selection was conducted by using geology, topography, soil and seasonal livestock migration (Kooch) maps. Information provided by the local experts was also implemented. A new site was selected, where the environmental conditions or land use history varied. Accordingly, 50 rangeland sites were selected from which 30 were located in rural and 20 in winter rangelands. Geographic distribution of rural rangeland sites were: 4 in

Marand, 9 in Kaleybar, 7 in Khoda afarin, 5 in Varzaqan and 2 in Jolfa. Sites of winter rangelands were scattered as 9 in Marand, 8 in Ahar, 2 in Varzaqan, and one in Kaleybar. Soil textures of most sites were silty loam, but in some places it was clay-loam or silty- clay-loam, pH was about 7-8, soil fertility was low to medium; nitrogen was highly limited whereas potassium was high nearly in all sites (Jankju et al., 2009). Plant species were identified by using some reference books (Akhani 2009; Assadi et al., 2001-2010; Davis 2007; Komarov et al., 1963-1974; Rechinger 1967-2010; Townsend et al., 2006; Tutin et al., 1964-1980); also by botanical identification in the Botanical Research Center of Ferdowsi University of Mashhad. Plant chorotypes were also determined for each plant species, by using several reference books (Akhani 2009; Assadi et al., 2001-2010; Davis 2007; Komarov et al., 1963-1974; Rechinger 1967-2010; Townsend et al., 2006; Tutin et al., 1964-1980; Zohary et al., 1980). Plant phenotypes were determined according to the Raunkiaer's life form specifications (Asri 2000). Plant chorotypes were identified based on Zohary (2004).

RESULTS

Floristic surveys on the winter and rural rangelands of Southern Ardabil Province (NAP) resulted in identification of 534 plant species, belonged to 315 genera, 68 families. Family name, Chorotype and Phenotype of each plant species are compared in the appendix. About 65% of the total plant species in NAP were belonged to the Irano-Turanian Chorotype, whereas Irano-Turanian-Mediterranean, Irano-Turanian-Mediterranean-Euro-Siberian, Irano-Turanian-Euro-Siberian and Pluriregional plant species respectively contained 11, 10, 6, and 5 percent of all plant species. Less than 3% of total plant species were belonged to the other Chorotypes like cosmopolitans and Subcomopolitans (Fig. 1).

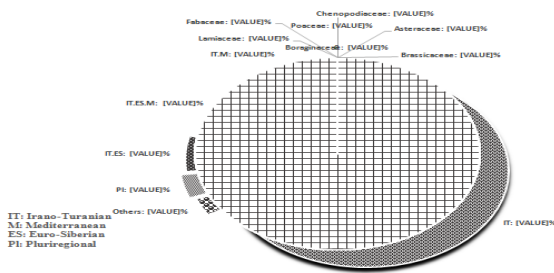

Fig. 1. Plant chorotypes and their relative percentage in flora of winter and rural rangelands in Southern Ardabil province

Plant classification, based on Raunkiaer's life forms revealed Hemicryptophytes as the most abundant (45% of total) species. Therophytes, Chamaephytes, Phanerophytes and Geophytes, only contained 32, 9, 7 and 7 percents of total plant species, respectively (Fig. 2). Among the 68 plant families found in the NAP, Asteraceae, Poaceae and Fabaceae were the most abundant. These families respectively contained 70 (13%), 61 (11%) and 50 (9%) species (Fig. 3).

Fig. 2. Plant life forms and their relative contribution (percent) in flora of winter and rural rangelands in Southern Ardabil Province

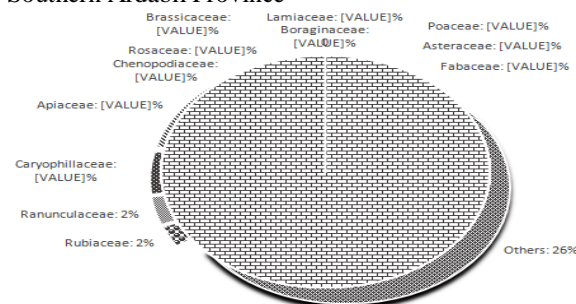

Fig. 3. Proportional contribution of plant families in flora of winter and rural rangelands in Southern Ardabil Province; Others: families less than 2% abundance Nevertheless, there were some shrubs e.g. *Juniperus excelsa*, *Berberis integrima*,

Cotoneaster spp., *Crataegus* spp., which are typical flora of Armeno-Iranian Phytochorion (Zohary 2004). Armeno-Iranian Phytochorion is one of Irano-Turanian's subdivisions. The presence of plants from other Phytochorions, are mainly due to interaction between three climate conditions; i.e. Mediterranean, Caspian Seas and Euro-Siberian. Hemicryptophytes and Therophytes were the most abundant life form in NAP. Several other studies in Ardabil Province have also reported higher abundance of Therophytes and Hemicryptophytes. Amiri et al. (2008) studied floristic of Tiregan in Hezar Masjed Mts. Memariani et al., (2009) also studied floristic of Fereizi in Chenaran, and both found higher abundance of Hemicryptophytes as compared to other life forms. In studies conducted at other parts of Iran, also higher fractions of Therophytes and Hemicryptophytes have been reported for the rangeland flora. In Genu at Hormozgan Nadjafi et al., (2006) and Garmsar at Semnan (Iranbakhsh et al., 2008) Therophytes were the most abundant life forms. In Fereizi at Azarbaijan, Therophytes and Hemicryptophytes were commonly the most abundant life forms (Memariani et al., 2009); in Khabr National Park and Rouchoun wildlife refuge (Irannezhad Parizi et al., 2010) and in Meimand (Vakili Shahrabaki et al., 2011) both in Kerman, and in Kalat highlands of Gonabad in Khorasan Razavi (Vaseghi et al., 2009) Hemicryptophytes were the most abundant plant life forms. Higher frequency of Therophytes and Hemicryptophytes in NAP can be related to their high adaptation to the Mediterranean climate conditions (Zohary 2004). The active growth periods of these life forms are concurrent with the rainy season in late winter and early spring (Tavili et al., 2009). During most of the summer and all winter times, Hemicryptophytes lose their aboveground parts while Therophytes remain as seed. Therefore, these plants avoid summer drought and winter cold stresses (Barbour et al., 1987). Chamaephytes are also Xerophytes plant and are geographically distributed within the whole NAP region. On the other hand, the mesic Phanerophytes and Geophyte

species were less abundant in the rural and winter rangelands of NAP; mainly found in the southern slope aspects or at the bank of seasonal water streams. In addition to the climate, intense grazing pressure can also be a determinant factor for the relative abundance and geographic distribution of different life forms (Heithschmidt and Stuth, 1991). Nearly the whole area of NAP is dominated by different species of *Artemisia* L., which contain lots of aromatic materials and essential oils (Cumming and Reid, 2008). Furthermore, thorny shrubs (e.g. *Astragalus* spp., *Acantholimon* spp., and *Acanthophyllum* spp.), poisonous plants (for instance *Euphorbia* spp and *Peganum harmala*) spiny forbs (e.g. *Cirsium* spp., and *Cousinia* spp.) and annual plants (such as *Eremopyron* spp. *Aegilops* spp. and *Bromus tectorum*) dominate vast areas of winter and rural rangelands in NAP. Aromatic and poisonous materials, and spins, or short life cycles are also plant adaptations to livestock grazing (Grime, 2007). In conclusion, winter and rural rangelands of NAP confer a relatively rich floristic composition, which is a result of plant responses to Mediterranean climate as well as intense livestock grazing. A combination of climate and land use impact has led to dominance of Hemicryptophytes and Therophytes, as well as vast distribution of Chamaephytes in the winter and rural rangelands of NAP. Climate has significant effect on the flora of all habitats in the NAP, whereas human impact is only significant on flora of rural rangeland.
